glin$deviance
## [1] 35.47649
glin$null.deviance
```

```
glin$null.deviance-glin$deviance
```

```
## [1] 102.5241
```

The change in deviance (94 on 1 df) is clearly very high showing an improvement of the model with a linear term over the null model (overwhelming evidence to reject  $H0: \beta_1 = 0$ )

But the actual deviance for the model is high 35.4764889 providing evidence against this Binomial model  $\chi^2_{8,0.9995}$ :

```
qchisq(0.9995,8)
```

```
## [1] 27.86805
```

5

Binomial model estimating  $\phi$  as  $D(y, \hat{\mu})/(n-p)$ .

```
glin$deviance / (glin$df.residual)
```

```
## [1] 4.434561
```

```
glq \leftarrow glm(p \sim 1 + x , weights = grain$n, data= grain, family=quasi) glq$deviance
```

```
## [1] 5.633424
```

6

Standard errors for parameter estimates are then multiplied by:

```
sqrt(glin$deviance / glin$df.residual)
```

```
## [1] 2.10584
```

7

Improvement over the null model on 1 df.

```
(glin$null.deviance-glin$deviance)/ (glin$deviance / glin$df.residual)
```

```
## [1] 23.11934
```

The scaled deviance for this model:

```
glin$deviance/(glin$deviance / glin$df.residual)
## [1] 8
qchisq(0.95,7)
## [1] 14.06714
sglin <- summary(glin)</pre>
with e.s.e(\hat{\beta_1}) =
sglin$coefficients[2,"Std. Error"]
## [1] 0.9810898
sglin$coefficients[2,"Std. Error"] * sqrt(glin$deviance / glin$df.residual)
## [1] 2.066018
ese_b=sglin$coefficients[2,"Std. Error"] * sqrt(glin$deviance / glin$df.residual)
So the wald test statistics
coefficients(glin)[2]
##
## 8.641606
coefficients(glin)[2] / ese_b
##
## 4.182735
t = coefficients(glin)[2] / ese_b
The slope is highly significant.
1-pt(t, df=7)
## 0.00206159
using quasi (same as subsection 5)
```

```
glq \leftarrow glm(p \sim 1 + x , weights = grain$n, data= grain, family=quasi)
summary(glq)
